

Geology and Quicksilver Deposits of the New Almaden District, Santa Clara County, California (Classic Reprint) (Paperback)

Filesize: 6.93 MB

Reviews

The publication is great and fantastic. I actually have read through and i am sure that i am going to planning to go through yet again yet again down the road. I realized this pdf from my dad and i encouraged this publication to understand.

Forgotten Books, United States, 2015. Paperback. Book Condition: New. 229 x 152 mm. Language: English . Brand New Book ***** Print on Demand *****.Excerpt from Geology and Quicksilver Deposits of the New Almaden District, Santa Clara County, California The New Almaden district, situated a few miles south of San Jose in Santa Clara County, Calif., has yielded nearly 40 percent of the quicksilver produced in the United States. The area mapped as the district for this report includes about 80 square miles, extending south from the flat Santa Clara Valley across the moderately low foothills containing the mines to the more rugged crest of the California Coast Ranges. The rocks underlying about three-fourths of the district. Including all of the mineralized area, are assigned on the basis of lithology to the Franciscan group of Late Jurassic and Cretaceous age. The only diagnostic fossils found indicate that the age of a part of the group is lower Upper Cretaceous (Cenomanian). The group consists of lithic and feldspathic graywacke, siltstone, dark altered volcanic rocks, chert, limestone, and a subordinate amount of metamorphic rocks, including glaucophane schists - an assemblage regarded as a typical eugeosynclinal suite. The thickness of the group cannot be determined accurately because of structural complexities, but the part present in the New Almaden district is believed to be at least 10,500 feet thick and may be much thicker. The sedimentary rocks are believed to have been derived from the rapid erosion of a rising landmass, and deposited in a subsiding trough which filled to wave base only in a few places near the end of the depositional period. The accompanying igneous activity included local outpourings of lava onto the sea floor and eruption of fragmental material of similar composition which accumulated as pyroclastic beds. The chert is abundant only...
